What is a battery pack calculator?

The core formula behind the Battery Pack Calculator is rooted in basic electrical principles. The primary equation is: Each component plays a crucial role in determining the overall energy available in a battery. For instance, consider a battery with a capacity of 10Ah and a voltage of 12V. The total energy would be calculated as 120Wh.

How to calculate the voltage of a battery in a series?

Even if there is various technologies of batteries the principle of calculation of power, capacity, current and charge and discharge time (according to C-rate) is the same for any kind of battery like lithium, LiPo, Nimh or Lead accumulators. To get the voltage of batteries in series you have to sum the voltage of each cell in the serie.

How do you calculate total energy in a cell pack?

In simple terms the total energy in the pack is just the total nominal voltage x total nominal capacity. Hence, you could have got to this point perhaps much faster, but I feel this is a good way of just working it through. Hopefully this gives you just a different view of the options and flexibility of different cell choices.

What does battery capacity mean?

Battery capacity, measured in ampere-hours (Ah), indicates how much charge a battery can hold and deliver over time. A higher capacity typically means longer runtime or duration before the battery needs recharging. For example, a 20Ah battery can theoretically deliver 20 amps for one hour, or 10 amps for two hours.

How do you calculate pack capacity?

The usable energy (kWh) of the pack is fundamentally determined by: $\text{Energy (kWh)} = S \times P \times \text{Ah} \times V_{\text{nom}} \times \text{SoC}_{\text{usable}} / 1000$ Note: this is an approximation as the nominal voltage is dependent on the usable window. Also, the variation in cell capacity will be needed to be understood to establish accurate pack capacity values in production.
